# Outline of the Talk

## Window Subsequence Matching

#### INPUT:

Text: COMPUTER SCIENCE IN RUSSIA Pattern: CES Window size: 10 TASK: to find substrings of the length at most 10 in the text that contains CES as a subsequence

#### OUTPUT:

#### 

Problem for this talk:

ch Window Problems for Compressed Texts

CSR'2006 2 / 1

CSR'2006 4 / 1

How given a COMPRESSED text to solve window subsequence matching faster than just "unpack-and-search"?

### Part I

What are **compressed** texts?

Can we do something interesting **without unpacking**?

Window Problems for Compressed Texts

## Straight-line Programs: Definition

for compressed texts

Our problem and our result

Sketch of the algorithm

	Example
Straight-line program (SLP) is a	abaababaabaab
Context-free grammar generating	$X_1 \rightarrow b$ $X_2 \rightarrow a$
exactly one string	$X_3 \rightarrow X_2 X_1$
Two types of productions:	$X_4 \rightarrow X_3 X_2$
$X_i  ightarrow a$ and $X_i  ightarrow X_p X_q$	$X_5 \rightarrow X_4 X_3$
	$X_6 \rightarrow X_5 X_4$

SLP = Compressed Text

**Fact [Rytter, 2003]:** given the archive of the text T compressed by LZ78,LZW or some dictionary-based method of original length n and the size of archive z we can in time O(z) convert it to SLP of size O(z) generating the same text.

Window Problems for Compressed Texts

**Fact [Rytter, 2003]:** given the LZ77-compressed or RLE-compressed text T of original length n and the size of archive zwe can in time  $O(z \log n)$  convert it to SLP of the size  $O(z \log n)$ generating the same text.

Further by compressed text we mean an SLP generating it

# Why algorithms on compressed texts?

Answer for algorithms people:

- Might be faster than "unpack-and-search"
- Saving storing space and transmitting costs

ski, Guessarian, Lifshits, Matiyasevich Window Problems for Compressed Texts

• Many fields with highly compressible data: statistics (internet log files), automatically generated texts, massage sequence charts for parallel programs

Answer for complexity people:

- Some problems are hard in worst case. But they might be easy for **compressible** inputs
- New complexity relations. Similar problems becomes different

### Problems on SLP-generated texts

### Part II

Our Problem and Our Result

Window Problems for Compressed Texts

CSR'2006 10 / 1

CSR'2006 12 / 1

CSR'2006 14 / 1

#### Window Subsequence Problems

**Definition:** w-window = substring of the length w**Definition:** minimal window = substring containing the pattern, but any substring of which does not contain the pattern

wich Window Problems for Compressed Texts

**INPUT:** SLP generating text *T*, pattern *P*, window size *w* 

#### Computational tasks:

- **(**) To decide whether pattern P is a subsequence of text T
- To compute the number of minimal windows of T containing P
- To compute the number of w-windows of T containing P

an, Lifshits, Matiyasevich Window Problems for Compressed Texts

### Window Subsequences: Motivation

Why do we do window subsequence matching (in compressed texts)?

- Variation of approximate pattern matching
- Useful for finding access patterns in databases
- Virus search in archives
- Pattern discovery in bioinformatics
- New step in the framework "what problems could be solved without unpacking?"

wich Window Problems for Compressed Texts

## Our Algorithm

## Main result:

Given a straight-line program of size m, a pattern of length k and an integer kwe can solve all window subsequence problems on SLP-generated text in time  $O(mk^2 \log k)$ 

evich Window Problems for Compressed Texts

## Part III

Algorithm for Window Problems on Compressed Texts

Window Problems for Compressed Texts

### Our Small Plan

- Define auxiliary data structures
- Compute them
- Derive answers for our tasks from these structures

### Auxiliary Arrays

Let  $X_1, \ldots, X_m$  be the nonterminals of SLP generating T, while  $P_1, \ldots, P_l$  be all different substrings of pattern P

#### Left inclusions

For every  $X_i$  and every  $P_j$  let us define L(i, j) as the length of the minimal **prefix** of  $X_i$  that contains  $P_j$ , in case of no such prefix exists let  $L(i, j) := \infty$ 

#### **Right inclusions**

For every  $X_i$  and every  $P_j$  let us define R(i,j) as the length of the minimal **suffix** of  $X_i$  that contains  $P_j$ , in case of no such prefix exists let  $R(i,j) := \infty$ 

Minimal windows

M(i) = number of minimal windows containing P in  $X_i$ 

**Fixed windows** 

F(i) = number of *w*-windows containing *P* in  $X_i$ 

# **Computing Minimal Windows**

We compute M(i) by induction on i and using already computed right/left inclusions:

wich Window Problems for Compressed Texts

CSR'2006 17 / 1

CSR'2006 19 / 1

CSR'2006 21 / 1

**Base:** if  $X_i \rightarrow a$ , then M(i) = 0 only except P = a, in the latter case M(i) = 1

Inductive step:  $X_i \rightarrow X_p X_q$ . M(i) = M(p) + M(q) + ??

#### Computing boundary minimal windows

- $\diamond$  Consequently consider decompositions  $P = P_{\mu}P_{\nu}$
- $\diamond$  For every decomposition with the help of L/R inclusions info
- \$\phi\$ find the unique minimal window such that
- $\diamond P_u$  is falling in  $X_p$  and  $P_v$  is falling  $X_q$
- If this window is shifted, then we increment the counter

Complexity: O(mk) Guessarian, Lifshits, Matiyasevich Window Problems for Compressed Texts

Summary

#### Main points:

- Compressed text = text generated by SLP
- Given SLP we can solve window subsequence matching in time  $O(mk^2 \log k)$
- Method: dynamic programming over SLP

#### **Open Problems:**

• Decrease the k-depended factor in complexity

an, Lifshits, Matiyasevich Window Problems for Compressed Texts

• To construct O(nm) algorithms for edit distance, where *n* is the length of  $T_1$  and *m* is the **compressed size** of  $T_2$ 

Computing Left Inclusions

We compute L(i,j) by induction on *i*:

**Base:** if  $X_i \to a$ , then  $L(i,j) = \infty$  for all  $P_i \neq a$ , and L(i,j) = 1 in case  $P_i = a$ 

**Induction step:** let  $X_i \rightarrow X_p X_q$ . If  $L(p,j) \neq \infty$ , then L(i,j) = L(p,j). Assume  $L(p,j) = \infty$ .

If we find a decomposition  $P_i = P_u P_v$  with minimal  $|P_v|$  where  $L(p, u) \neq \infty$  and  $L(q, v) \neq \infty$ . then we immediately get  $L(i,j) = |X_p| + L(q, v)$ 

Such a decomposition can be found by a binary search Total complexity  $O(mk^2 \log k)$ where m is the size of SLP and k is the length of the pattern Mikhail Dvorkin: O(mk<sup>2</sup>)

ian, Lifshits, Matiyasevich Window Problems for Compressed Texts

## Deriving the Answer

#### Computational tasks:

- To decide whether *P* is a subsequence of *T* • Answer: "yes" iff  $M(m) \neq 0$
- To compute the number of w-windows of T containing PAnswer: F(m)
- To compute the number of minimal windows of T containing P • Answer: M(m)

ch Window Problems for Compressed Texts

Complexity:  $O(mk^2 \log k)$ .
